Are storing energy and discharging electricity similar?

In terms of storing energy or discharging electricity, they are similar, it is simply a question of whether or not the chemical processes involved permit multiple charging and discharging. If you're enjoying this article, consider supporting our award-winning journalism by subscribing.

Does a battery store charge?

This work, which is done on the electric charges that are on the positive terminal, results in accumulation of potential chemical energy in the battery, since it causes the reversal of the chemical reactions that release energy. So, a battery does not store charge but rather energy.

Does a battery store electric potential energy?

We can't say that the battery stores electric potential energy. A battery tends to maintain the electric potential energy at each of its terminals, but the energy stored in the battery is not from the separation of charges, it's from the redox reactions (chemical energy).

What happens if a battery is discharged?

A "charge" of chemical energy is stored in the battery, but electrical charge is not. And when a battery is being "discharged", its chemical fuel drives a process which pumps charge through the battery. During discharge the battery's fuel will eventually be exhausted, but the total electric charge within the battery will never decrease!

How does a battery store electrical energy?

For now, I have this: A battery stores potential chemical energy (potential energy because it is not being used, but can be used to do work), which can be converted into electrical energy by chemical reactions that occur inside it. This conversion happens when it is connected to a circuit.
