How does a hybrid absorption heat pump work?

The hybrid absorption heat pump provides both cooling and useful high-temperature heat with the same driving heat, releasing waste heat at ambient temperature. The cooling, release of waste heat, and production of useful heat are achieved by heat transfer with external fluids, which are chilled water, cooling water, and hot water, respectively.

Should you choose a hybrid cooling and heating absorption heat pump?

However, absorption chiller has a low operating time, except in summer, leading to a long payback period for the system. Thus, a hybrid cooling and heating absorption heat pump can be a reasonable solution for increasing the annual rate of operation of the absorption cycle.

What is a hybrid cooling/heating absorption heat pump cycle?

The hybrid cooling/heating absorption heat pump cycle comprised eight heat exchanger elements, solution and refrigerant pumps, and three expansion valves. The cycle comprised three pressure levels: low, medium, and high. The absorbent solution circulates in the order of the generator, low-pressure absorber, high-pressure absorber, and generator.

How does a total UA affect a hybrid absorption heat pump?

The total UA determines the size and cost of the hybrid absorption heat pump, which physically evaluates the feasibility of the system. The total UA rises exponentially as the refrigerant distribution ratio decreases and the solution circulation ratio increases.
