

How to improve the energy storage of inductive components

How do inductors store energy?

The energy stored within an inductor is directly related to its inductance and the amount of current flowing through it. Unlike resistors which dissipate energy as heat, an ideal inductor stores energy in its magnetic field when current passes through its coil.

What is the formula for energy stored in an ideal inductor?

The formula for the energy stored in an ideal inductor is derived from the power absorbed by the inductor as current builds up within it. The instantaneous power in an inductor is $P=V \cdot I$, and since $V=L \frac{dI}{dt}$, the power is $P=L \frac{dI}{dt} I$. Integrating this power over time as the current increases from zero to a steady value I gives the total energy stored.

How does Linear Technology affect inductor energy storage?

While one inductor's current is increasing, the other's is decreasing. There is also a significant reduction in the required inductor energy storage (approximately 75%). The inductor's volume, and therefore cost, are reduced as well. See Linear Technology's Application Note 77 for complete details.

How does an inductor work?

Unlike capacitors which store energy in an electric field between two conductive plates, or batteries which store energy chemically, an inductor converts electrical energy into magnetic potential energy. When current flows through its coil, it generates a magnetic field in the surrounding space and, often, within a ferromagnetic core.

How do inductor ripples affect energy consumption?

The output ripple is reduced in a similar fashion. While one inductor's current is increasing, the other's is decreasing. There is also a significant reduction in the required inductor energy storage (approximately 75%). The inductor's volume, and therefore cost, are reduced as well.

How does a solar energy storage inductor work?

In this topology, the energy storage inductor is charged from two different directions which generates output AC current. This topology with two additional switching devices compared to topologies with four switching devices makes the grounding of both the grid and PV modules. Fig. 12.
